

Compact structures of extragalactic radio sources in the cosmological context

Cosmo Cruise
2015

September 2 - 9, 2015

Leonid Gurvits

*Joint Institute for VLBI European Research Infrastructure Consortium, The Netherlands
Dept of Astrodynamics and Space Missions, Delft University of Technology, The Netherlands*

Angular size – redshift (θ – z) tests: the concept

- The idea:
F. Hoyle, 1959, URSI Symp. No. 1, Paris
 - **Many attempts at arc-second scale:**
 - Radio structures as standard rods
 - Kapahi 1987
 - Barthel and Miley 1988,,
 - Nilsson et al 1993
 - + many others
 - **Strong source evolution found !**
 - Some encouraging results by
 - Buchalter et al. 1998
 - Daly et al. 2001, 2002
- (hand-picking “right” sources)*

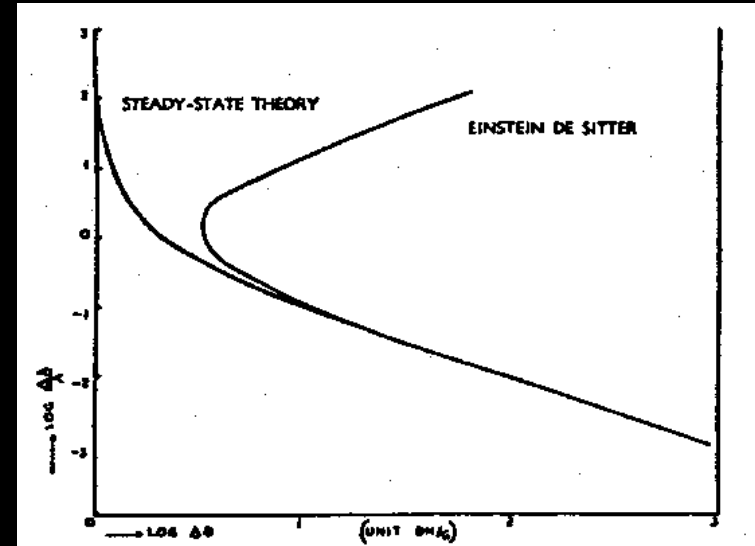

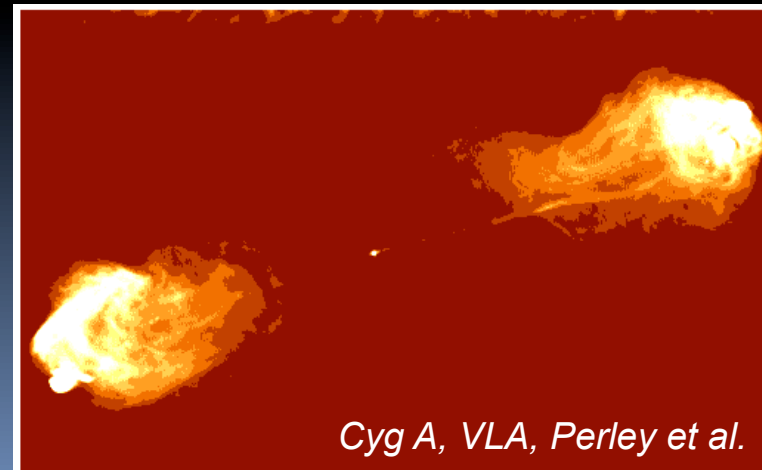

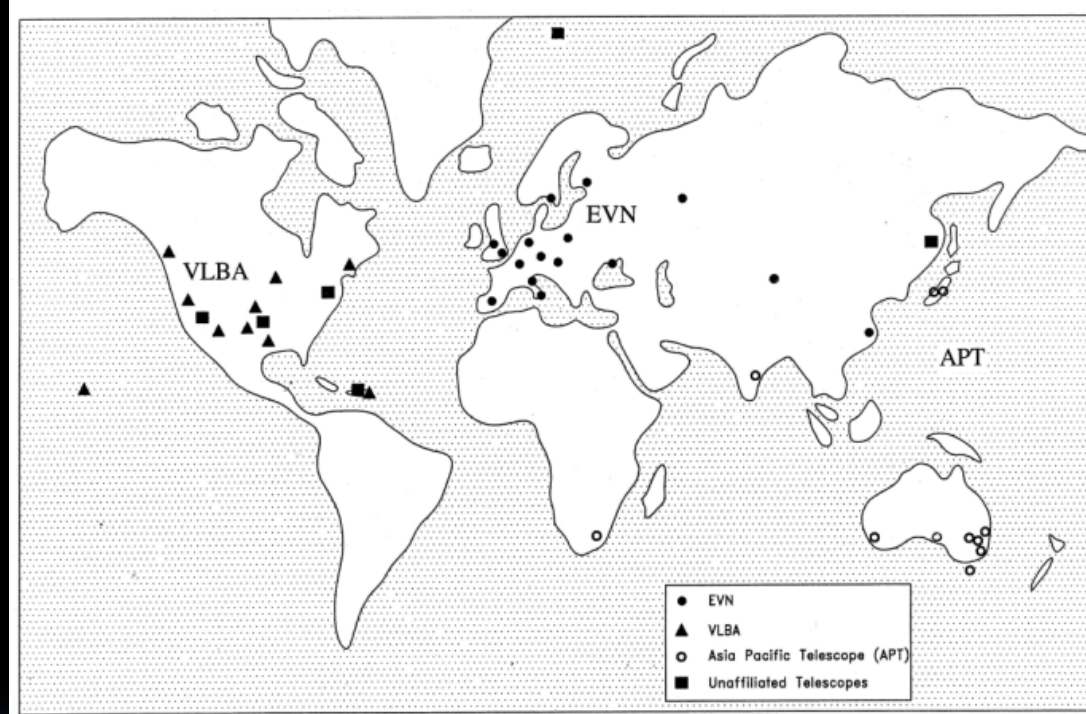

FIG. 5. Apparent diameter $\Delta\theta$ of a source of absolute diameter D , plotted against redshift.

Very Long Baseline Interferometry (VLBI): the highest [imaging] angular resolution in astronomy

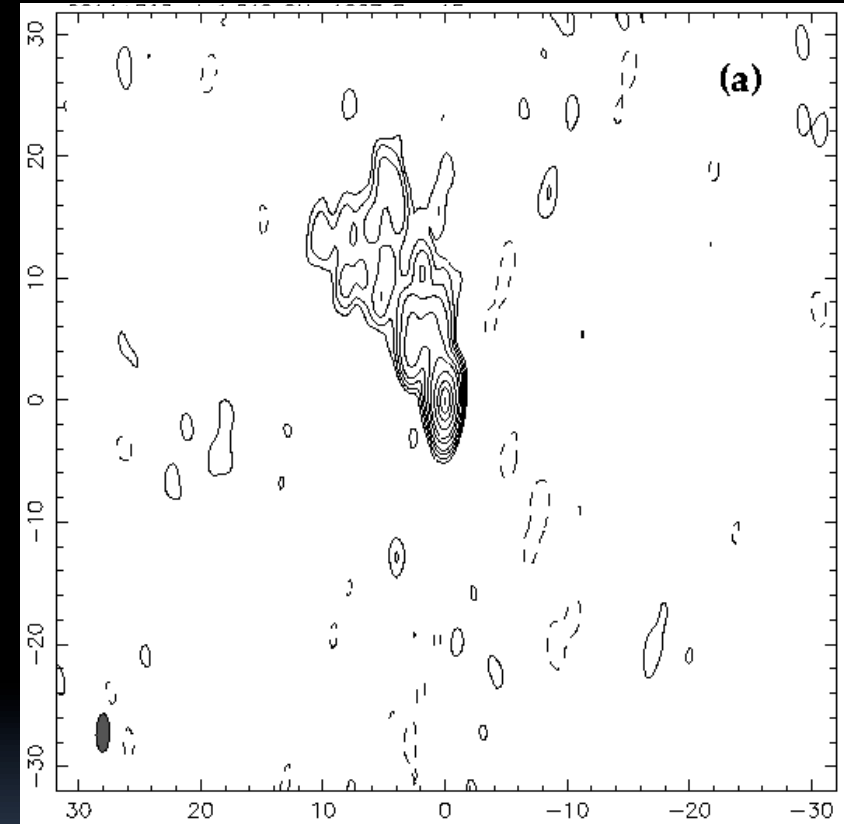

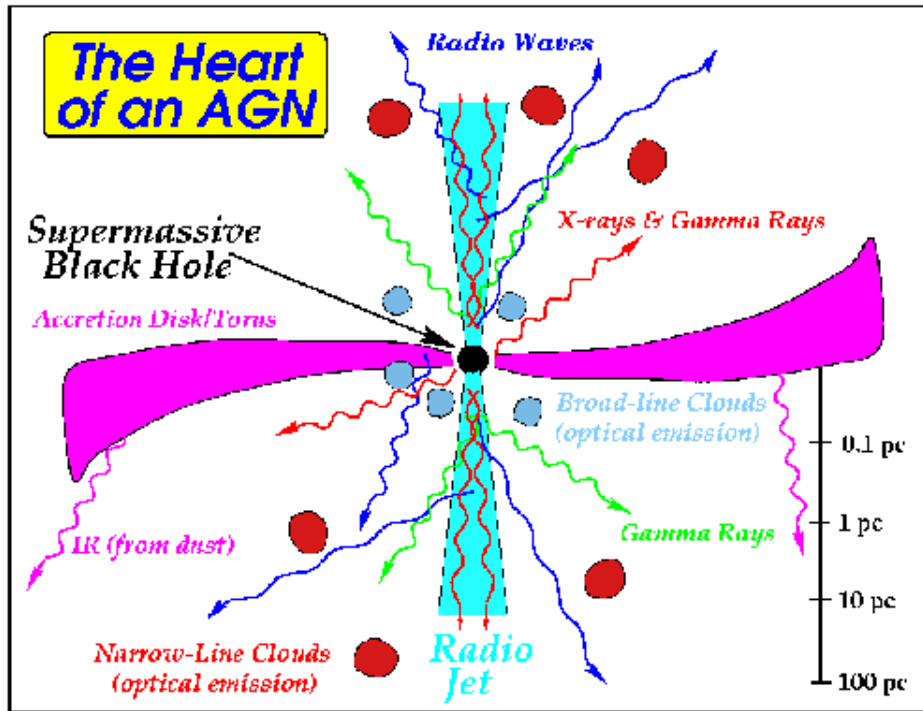

At present:

- VLBI covers wavelengths from ~ 0.9 m (~ 327 MHz) to ~ 1 mm (~ 300 GHz);
- Angular resolution from 100 to 0.1 milliarcsecond (mas).

• Plus: Space VLBI – baselines up to ~ 30 Earth diameters

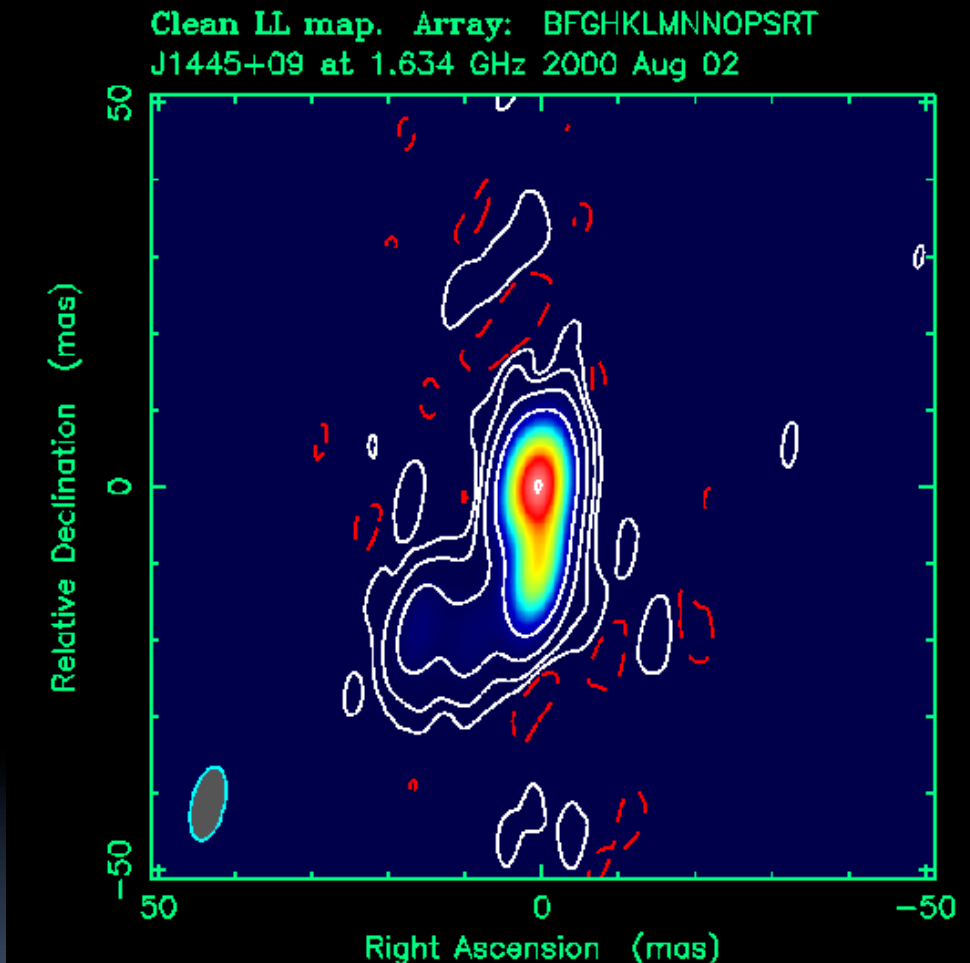

What you [want to] get versus what you see:

ARISE, 1999, JPL Publ. 99-14

- What is the correspondence between the two pictures (jets, cores, etc.)?
- How much deeper in the “core” can one go (a hunt for the highest T_B)?

What is seen in AGN at the milliarcsecond scale?

- “Core-jet” structures composed of components with $T_B \sim 10^8 - 10^{13}$ K
- These components are “short-leaving” (comparing with the cosmological scale): 10^3 vs 10^{10} yrs
- Central engines of AGN powered by supermassive black holes
- Physics on the sub-pc scale is likely to be dominated by the gravitational potential of the central BH

Physical size (scale) of AGN as a class is more or less the same?

Why mas-scale cosmology?

- The age of “precision cosmology” (M. Longair, IAU GA 2000)
- VLBI – the leading edge of (imaging) precision in astronomy
 - Parsec/sub-parsec linear resolution ANYWHERE in the Universe;
 - Objects – the most powerful “engines” of the Universe, AGN
 - *Their physics supposed to be “governed” by gravitation*
 - Well understood?
- Cosmological “utilisation” of existing VLBI data possible
- In combination with other techniques, VLBI provides unique tools for measuring cosmologically meaningful phenomena (e.g. H_0 from the megamaser in NGC4258)
- “Angular size–redshift” (θ - z) milliarcsecond scale test
 - *“in action” since ~1992 (Sahni & Starobinsky 2000, Int. J. Mod. Phys D, 9, 373)*

Standard rod at mas scale: *phenomenology*

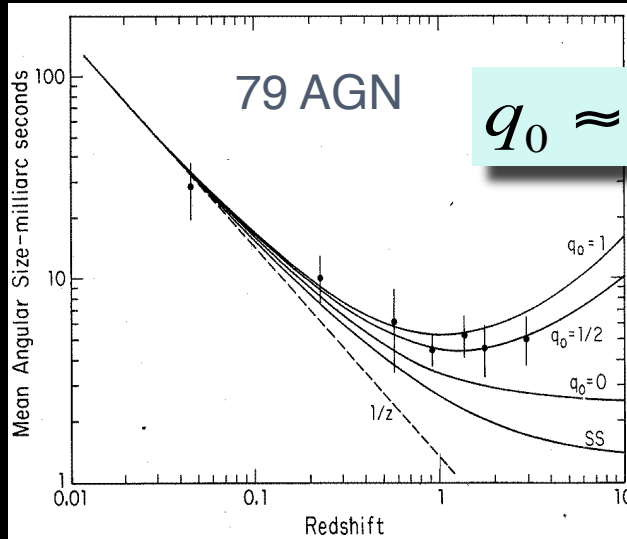

$$\theta = \frac{H_0}{c} l \left(\frac{L_c}{L_0} \right)^\beta (1+z)^n D$$

$$D = D(z, \text{cosmology})$$

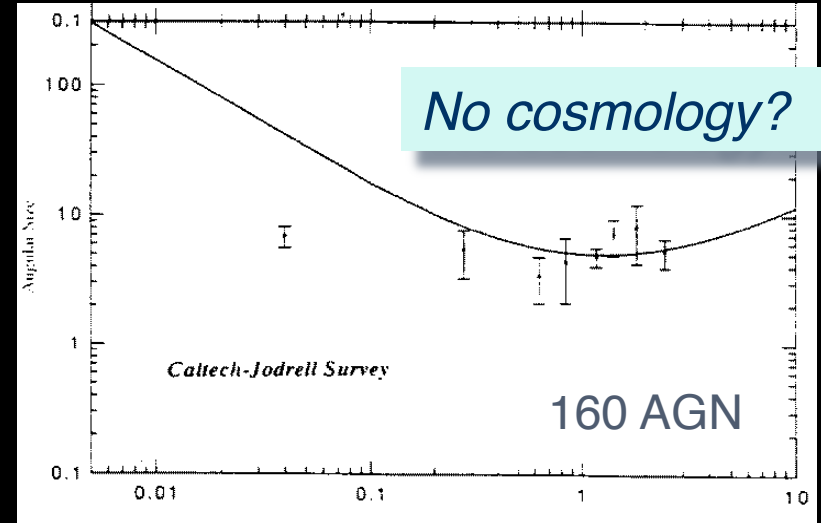

- β – physics of AGN (after all, AGN are different)
- n – a blend of (class) evolution and AGN physics
- θ and z are measurables =>
 - a fit of “ θ – z ” enables estimates of D

NB: *Collecting “ θ – z ” data can be done in ad hoc fashion, not a special project/mission*

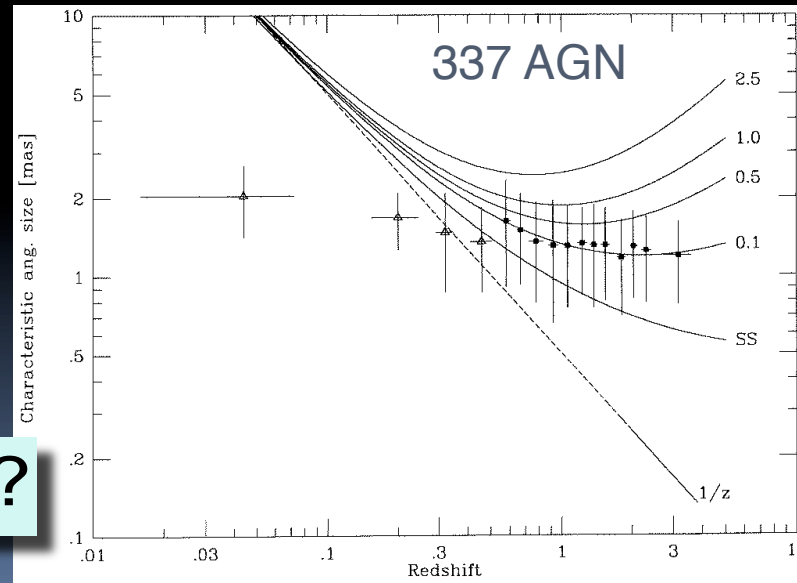

Demonstration mas-scale θ -z tests (1990s)

Kellermann 1993

Pearson et al. 1996
Wilkinson et al. 1998

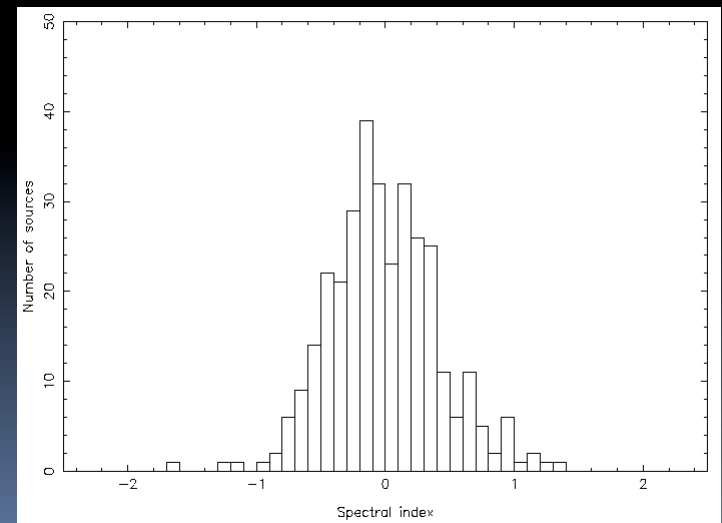

$q_0 < 0.5?$

LIG 1994

θ - z 2000: “maximum” use of ad-hoc data

- 330 sources with known redshift and mas images at 5 GHz better than 100:1
- 4-parameter regression model (“proof of suitability”)

LIG, Kellermann, Frey 1999

Naïve results

Table 1: Two-parameter (l_k and q_0) regression model results with 1σ errors for different, fixed values of β and n for the sample of 145 sources ($L_k^2 \leq 10^{26}$ W/Hz, $-0.38 \leq \alpha \leq 0.18$).

n		$\beta = -0.20$	$\beta = -0.10$	$\beta = -0.05$	$\beta = 0.0$	$\beta = 0.05$	$\beta = 0.10$	$\beta = 0.20$

$$q_0 \leq 0.5 \text{ for } \beta + n \geq -0.15$$

Aftermath of the “maximum use” sample publication

Vishwakarma 2001 a,b
Astro-ph/9912105, -/0012492,

$$1 + \Omega_{k0} = \Omega_0 + \Omega_{\Lambda 0}, \quad 2[q_0 + \Omega_{\Lambda 0}] = \Omega_0$$

- Re-analysed data from LIG 1994 (256 sources) and LIG, Kellermann and Frey 1999 (330 sources) in concurrence with the Type Ia SN (Riess 1998, Perlmutter et al. 1999)
- Various models analyzed:

models	Ω_0	Ω_0	$\Omega_{\Lambda 0}$
	flat	global	
$\Lambda \sim S^{-2}$	0.68	0.97	0.61
$\Lambda \sim H^2$	0.67	0.29	1.03
$\Lambda \sim \rho$	0.67	0.53	0.82
$\Lambda = \text{const}$	0.2	0.08	1.16

θ -z data favor accelerating and decelerating models with $\Lambda = \text{var}$ or accelerating models with $\Lambda = \text{const}$ (SN Ia data: acceleration in both cases)

Aftermath of the “maximum use” sample publication

Chen & Ratra 2002
Astro-ph 0207051

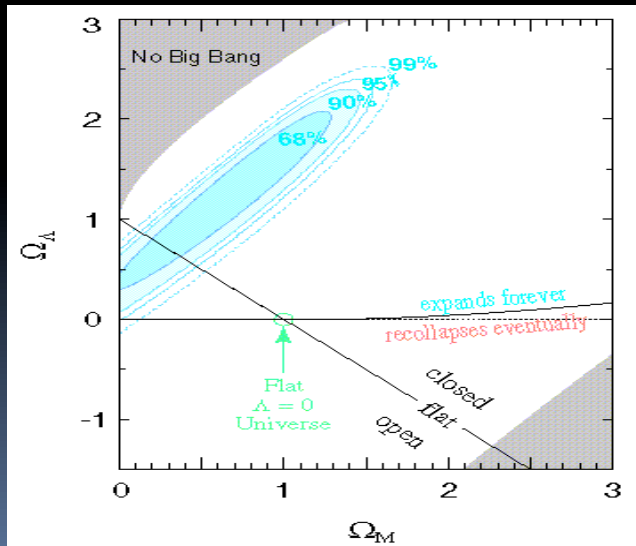

- Minimize

$$\chi^2(l, P) = \sum_{\text{bins}} \left[\frac{\theta(l, P, z_i) - \theta_{\text{obs}}(z_i)}{\sigma(z_i)} \right]^2$$

$$L(P) = \int dl e^{-\chi^2(l, P)/2}$$

- Treat linear size, lh , as a “nuisance” parameter

Perlmutter et al. 1998

Constraints on cosmological model from θ - z data are consistent but less constraining than those of SN Ia.

Aftermath of the “maximum use” sample publication

Lima & Alcaniz 2002

- FRW model driven by non-relativistic matter and a smooth “dark energy” component $p_x = \omega \rho_x$
- Best fit:

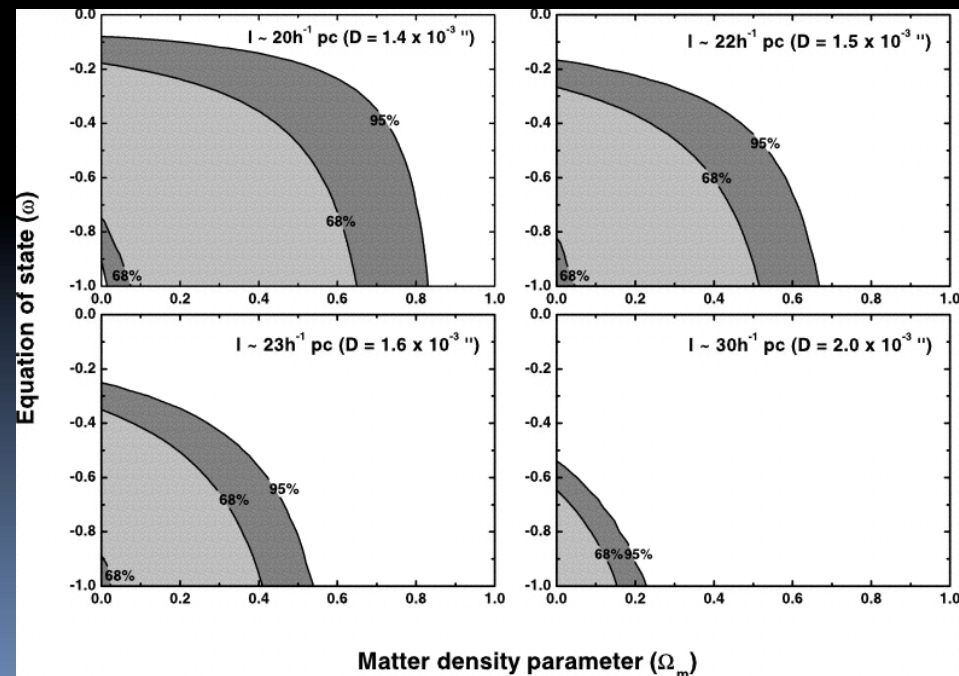

$$\Omega_m \leq 0.62, \quad \omega \leq -0.2, \quad lh = 20 \text{ pc}$$

$$\Omega_m \leq 0.17, \quad \omega \leq -0.65, \quad lh = 20 \text{ pc}$$

Conventional flat Λ CDM model ($\omega = -1$) with $\Omega_m = 0.2$ is the best fit.

Better statistics –
– more data needed!

Shocks in jet as standard rods: θ/τ_{int} versus z

- Linear size of shocks depends on the variability time-scale, τ_{int}
- Angular size of the shocks, θ , measured by VLBI (typically 0.1 mas)
- The ratio, θ/τ_{int} , serves as a standard object
- The method requires both VLBI data and monitoring (at high frequencies)

$$q_0 \approx 0, \quad \Omega_m \approx 0$$

$$\Omega = \Omega_m + \Omega_\Lambda = 1$$

Wiik & Valtaoja, 2001

Fig. 2. Normalized datapoints and fitted models with $\Lambda \neq 0$ (Eq. (7)). Ω_m was fixed and best fit was found with $2^{-2/3} K H_0$ as the free parameter

Half a century of quasars

- 3C 273, 1963 – (the story by Hazard et al. 2015)
- AGN of all kinds
- Central SMBH
- Known through $z \sim 7$

(cf. SN I, $z \sim 2$)

- Earth-based VLBI offers parsec-scale imaging
 - but deals with a “smoking gun” only....
- VLBI surveys provide images of several 10^3 sources
 - including ~ 30 sources at $z > 5$
 - cover received frequency range 1.6 – 22 GHz
 - push the radio brightness envelope...
- Key improvements for $\theta-z$ tests with AGN VLBI images
 - *Higher z (efforts underway; several $z > 6$ QSOs imaged)*
 - *Higher sensitivity (efforts underway; single-digit mJy sources imaged)*
 - *Sharper view (higher brightness temperature) – needed!*

Cosmic conspiracy: *Earth, a very special place*

But not because of this only

Brightness temperature of a slightly resolved source:

$$T_b = \frac{2 \ln 2 S_{\text{core}} \lambda^2 (1+z)}{\pi k \theta_{\text{maj}} \theta_{\text{min}}}$$

$\sim B^2$

For a “typical” AGN:

$$z \sim 1$$

$$S_{\text{core}} \sim 500 \text{ mJy}$$

$$T_b \sim 10^{12} \text{ K (Inverse Compton limit, Kellermann & Pauliny-Toth 1969)}$$

$$B \sim 10^4 \text{ km}$$

Earth, a very special VLBI system!

RadioAstron – Spektr-R

- 10-m antenna
- 0.327, 1.6, 5 and 22 GHz
- Dual-polarization
- 128 Mbps
- 2 on-board H-masers
- Apogee (initial) – 343,000 km
- Data reception – Pushchino
– Green Bank

In orbit since 18 July 2011 (*under development since 1978*)

**Baikonur,
18 July 2011
02:31 UTC**

RadioAstron AGN Survey

- 270 brightest AGN from Earth-based surveys
 - $S_{\text{corr}} > 600$ mJy at the longest Earth-based baselines (8 GHz)
 - Plus several targets of special interest (IDV and high- z sources)
 - Plus 20 highest kinematics AGN from 15 GHz MOJAVE (Lister+ 2003)
- Status as of April 2015:
 - 1100 segments (experiments) processed;
 - 360 detections on **90 sources**
- Detection records:
 - 18 cm: 0048–097 $27 D_{\text{Earth}}$
 - 6 cm: 0716+714 $23 D_{\text{Earth}}$
 - 1.35 cm: OJ287 $15.5 D_{\text{Earth}}$ (fringe spacing $\sim 14 \mu\text{as}$)

How high can be T_B in AGN?

Theory:

Inverse Compton Cooling: $T_B \leq 10^{11.5}$ K

Kellermann & Pauliny-Toth 1969

Equilibrium ($E_p = E_m$): $T_B \leq 10^{10.5}$ K

Readhead 1994

Observations:

TDRSS OVLBI: $T_B \geq 10^{12}$ K

Linfield et al. 1989

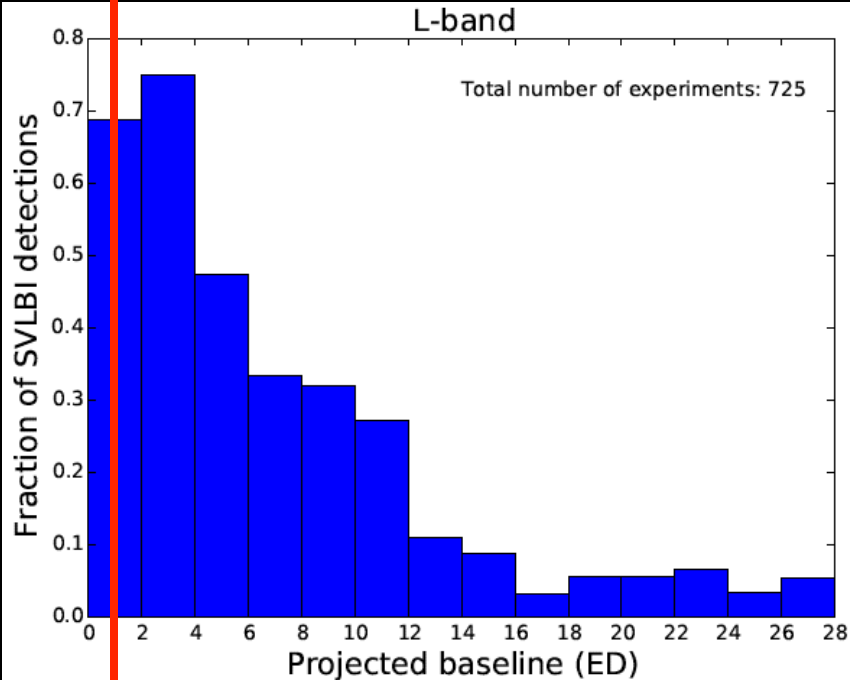

VSOP, AO0235+164: $T_B \geq 6 \times 10^{13}$ K

Frey et al.. 2000

VLBA, 2 cm survey: $T_B \geq 3 \times 10^{12}$ K

Kovalev et al.. 2006

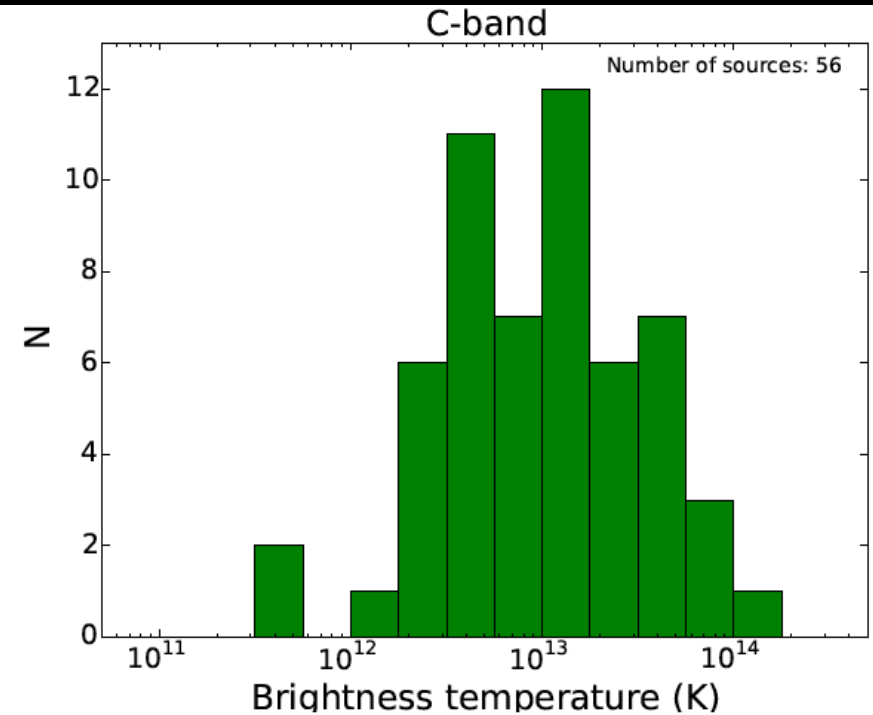

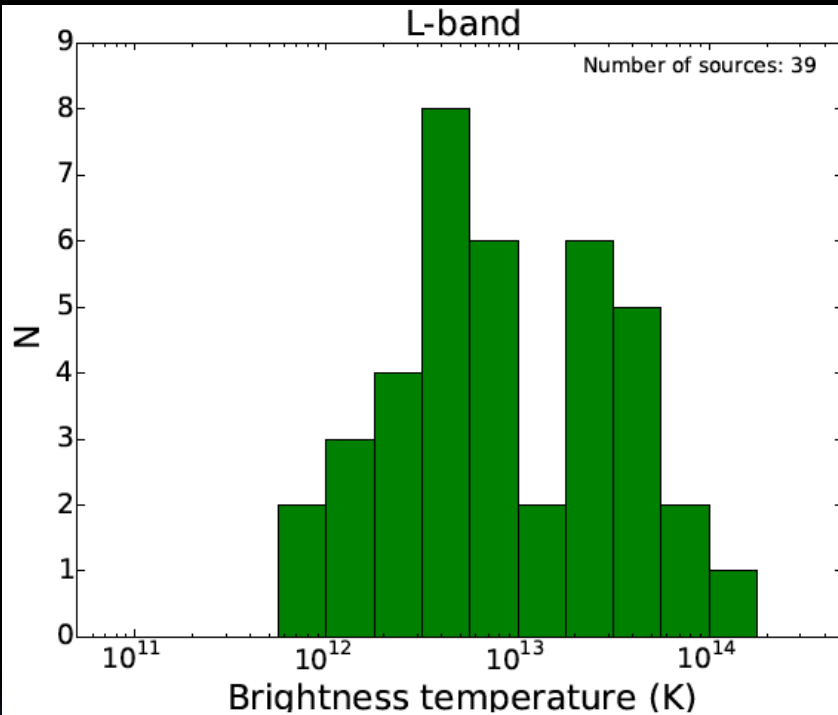

AGN Survey detectability statistics so far

Earth diameter

Qualitative conclusion: no surprises, but...

Brightness temperature in RA AGN Survey

- RadioAstron can detect $T_B \sim 10^{15} - 10^{16}$ K
- So far – no such detections

RadioAstron measurements of 3C273

λ [cm]	GRT	B	S_B [mJy]	θ μ asec	T_B [K]
18	GBT Arecibo	165,000 km 0.9 Giga λ	65 ± 10	270 ± 10	10^{14}
6	Arecibo	84,500 km 1.6 Giga λ	130 ± 20	150 ± 10	3×10^{13}
1.3	GBT/ VLA	99,300 km 7.6 Giga λ	250 ± 40	22 ± 2	2×10^{13}

Observed T_B is 10^2 to 10^3 times higher than the theory predictions

How can this be?!

- Relativistic Doppler boosting

- $T_{\text{obs}} \equiv \delta T_{\text{int}} \sim \gamma T_{\text{int}}$

- $\gamma \sim 15$

- $v_p \neq v_b?$ **NO!**

- Complex geometry

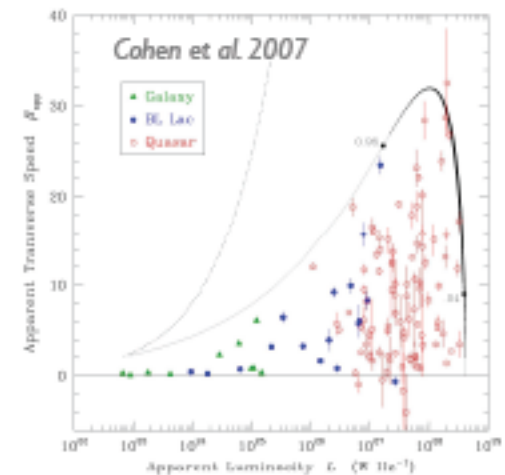

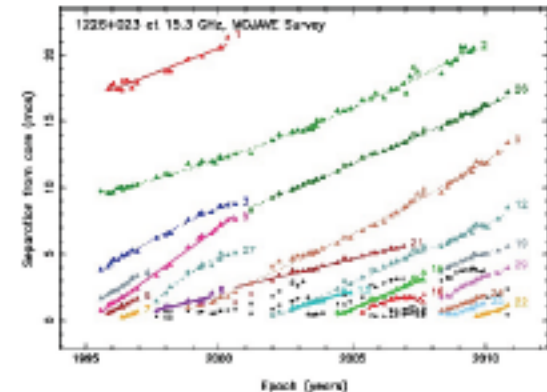

- Non Stationary Processes (acceleration/injection)

- Proton synchrotron radiation

- $T_b(p)/T_b(e) = (m_p/m_e)^{9/7} \sim 10^4$

- Coherent emission

- Stimulated (maser) emission

In lieu of conclusions

- AGN cores are compact enough to require $B \sim 10 D_{\text{Earth}}$
- For ~ 70 AGN observed so far, $T_B \sim 10^{12} - 10^{14}$ K
 - *very high Doppler boosting?*
 - *(en-mass) exotic explanations?*
 - *truly new physics?*
- Completion of RadioAstron AGN Survey in combination with massive (thousands of sources) Earth-based AGN VLBI surveys will offer a reliable “ $\theta-z$ ” database for ad hoc cosmology tests – at least consistency check.
- Wanted: insight by cosmology community
